

SYNTHETIC PATIENT RECORD - SOFTWARE TESTING ONLY

Patient Medical Chart

Suncoast Comprehensive Stroke Center | Emergency Neurology and Neurointervention | Florida

1. Patient and coverage information

Patient	Marcus Daniel Lee	DOB / age	1961-09-03 / 64
Member ID	FLB-SYN-1003	Plan	Florida Blue PPO (synthetic)
Chart ID	SCSC-2026-0715	Encounter	2026-07-15
Clinician	Nina Shah, MD	Location	Orlando, FL

2. Prior authorization request

Procedure	Endovascular mechanical embolectomy for acute ischemic stroke	CPT	61645
Diagnosis	Acute left middle cerebral artery occlusion	ICD-10	I63.512
Target	Proximal left M1 segment	Requested	Emergent, 2026-07-15
Authorization	Emergency retrospective review	Payer	Florida Blue

3. Stroke timeline and neurological deficit

Time	Event	Finding
06:20	Last known well	Normal speech and right-sided strength
07:05	Emergency department arrival	Aphasia, right facial droop, right arm and leg weakness
07:18	NIH Stroke Scale	NIHSS 16; substantial clinically significant deficit
11:40	Neurointerventional decision	Planned thrombectomy 5 hours 20 minutes after onset

4. Imaging available in the chart

CTA head demonstrates an occlusion of the proximal left M1 segment of the middle cerebral artery, within the proximal intracranial anterior circulation.

Noncontrast CT shows no intracranial hemorrhage. CTA shows no arterial dissection.

A CT perfusion study was reportedly performed at the transferring facility, but the source images and final neuroradiology report are not present in this chart. No ASPECTS score, ischemic-core volume, penumbra measurement, or other documented evidence of salvageable brain tissue is available for review. Salvageable tissue must not be inferred from the other findings.

5. Treatment and transfer documentation

The patient received tenecteplase at 07:32 after standard screening. There was no clinical improvement before transfer. Blood pressure was managed per stroke protocol.

The receiving neurointerventional team planned FDA-cleared mechanical thrombectomy within 12 hours of symptom onset based on the M1 occlusion and NIHSS 16. The missing perfusion/ASPECTS documentation remained unresolved at the time of retrospective review.

6. Documentation gap

The chart establishes proximal anterior-circulation occlusion, treatment timing within 12 hours, substantial neurological deficit, and absence of hemorrhage or dissection.

The chart does not establish the mandatory criterion of salvageable brain tissue in the affected vascular territory. A signed ASPECTS or perfusion interpretation is required to complete the review.

Attestation: This is a wholly fictional record created for software regression testing. It must not be used for clinical care, billing, or coverage determination.
